Oligodendrocyte Making Myelin

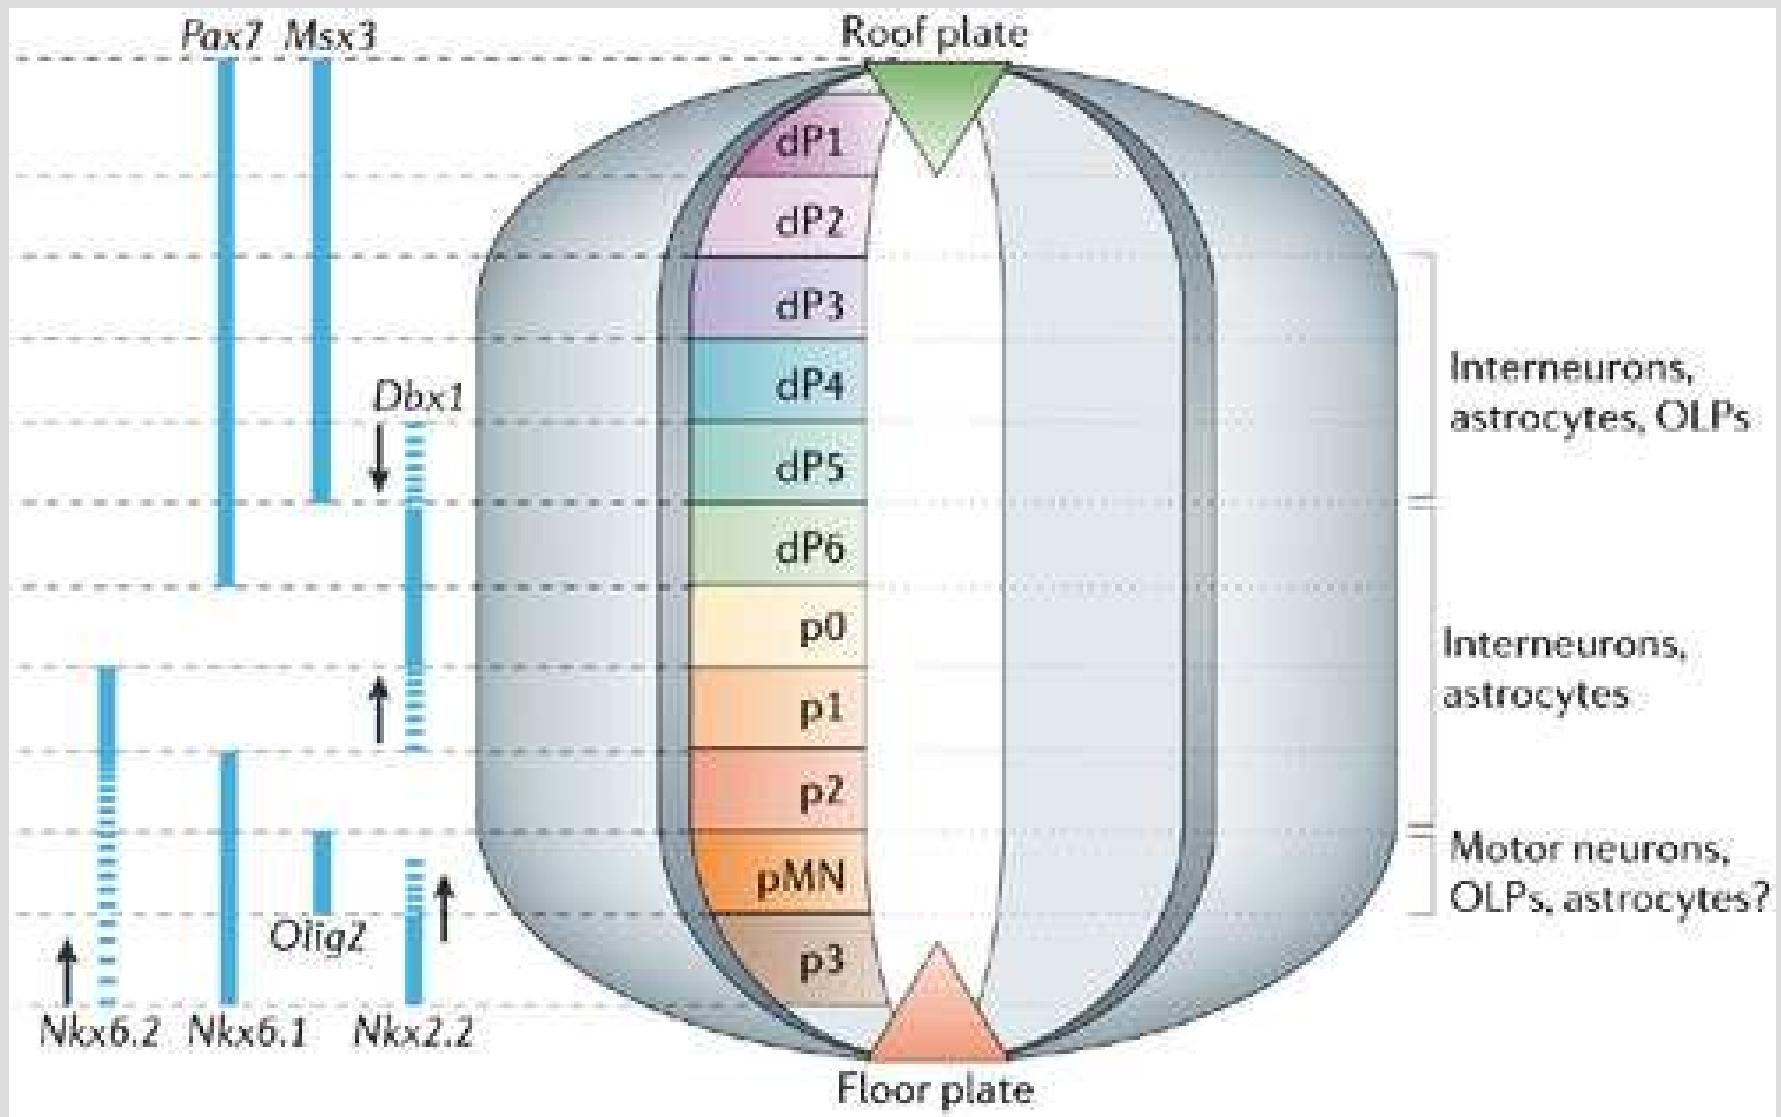

Mielin-hüvely

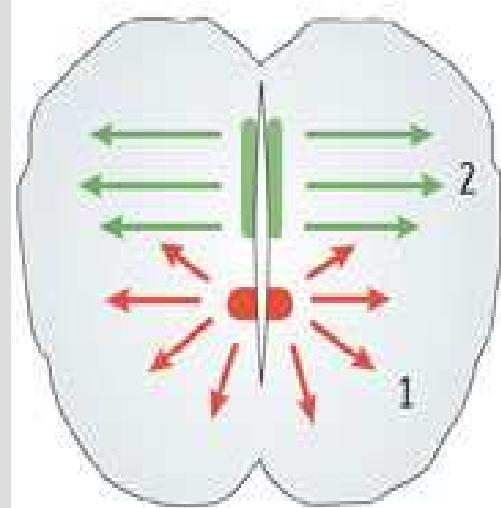

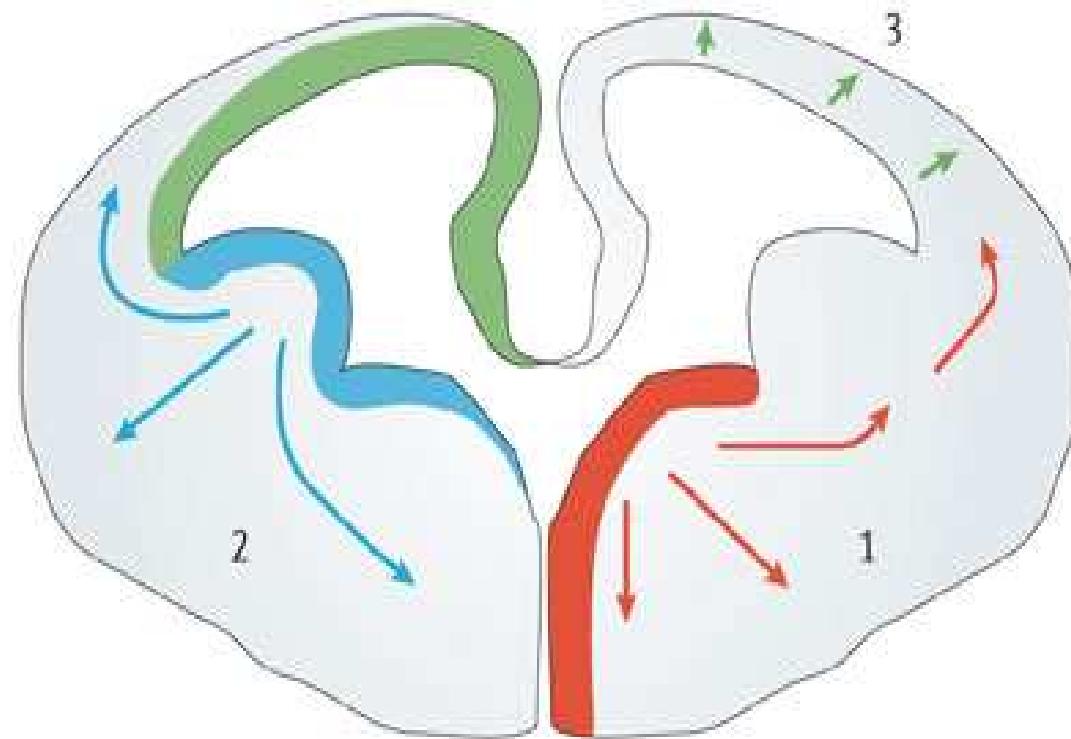

Axon vezetés sebessége lehet akár 100 m/sec (360 km/óra)

Gerinctelenekben: vezetési sebesség növelése az axon-átmérő növelésével.
Max. Vezetési sebesség ~ 25 m/sec (90 km/óra)

- **a | In the mouse spinal cord,** 85% of oligodendrocyte precursors are generated from pMN in the ventral ventricular zones (1), starting at about embryonic day (E)12.5. At about E15, generation of a secondary wave of precursors starts in more dorsal regions^{16, 17, 18} by trans-differentiation of radial glia¹⁸ (2).
- **b | In the telencephalon,** the ventral-most precursors in the medial ganglionic eminence are produced from about E12.5 (1), production of the lateral ganglionic eminence-derived precursors starts a few days later (2), and production of the cortex-derived precursors occurs mainly after birth¹⁹ (3).

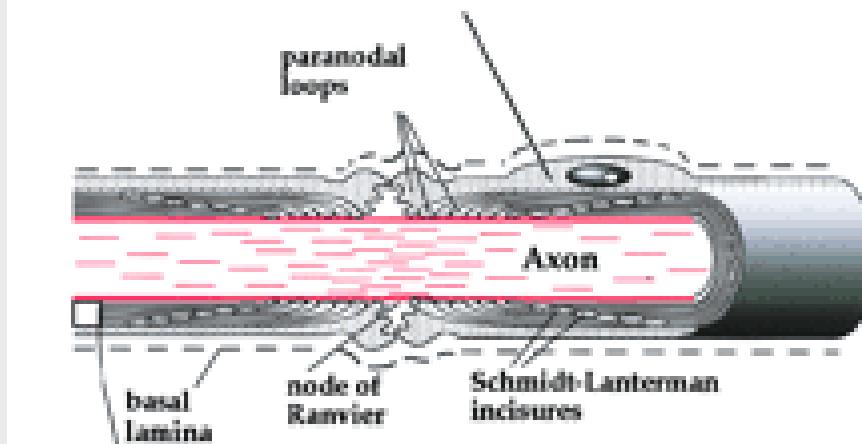

Ventral origin of PDGFR α -positive oligodendrocyte precursors.

Current Opinion in Neurobiology

Nogo-A, MAG and OMgp, the principal inhibitors of neurite growth in CNS myelin, interact with a receptor complex comprising NgR, p75 and additional components. Methods of blocking Nogo and its actions are shown in red. As well as gene deletions (Nogo-KO), Nogo-A, which is shown with its two main active sites facing the extracellular space, can be neutralized by specific antibodies or by a soluble Nogo-66-binding fusion protein comprising domains of the receptor subunit NgR. The NgR subunit itself can be blocked by the NEP1-40 peptide derived from the first 40 amino acids of the Nogo-66 region of Nogo-A. As MAG and OMgp also bind to NgR, NEP1-40 may be a particularly potent reagent. Nogo-A and Nogo-66 activate Rho-A and its downstream target ROCK, the activity of which can be blocked by C3 transferase and the inhibitor Y27632, respectively.
